Cancer is a class of diseases in which abnormal cells divide without control and are able to invade other tissues. Cell proliferation plays a role in many physiological processes ranging from development to the repair of damaged tissues. There are many mechanisms for keeping cell proliferation under tight control. For instance, the activities of the proto-oncogenes are balanced by the action of tumor suppressors. DNA damage and repair mechanisms exist in order to decrease the likelihood of genetic mutation and cell transformation. In addition, the immune system is designed to recognize and destroy cancerous cells. Accumulating disruptions in these homeostatic control mechanisms can lead to unregulated proliferation and cancer.

CUSABIO offers a variety of tools for studying many areas of cancer research including apoptosis, angiogenesis, biomarker, signal transduction, and so on.

**Apoptosis**

Apoptosis is the process of programmed cell death that is a normal component of the development of multicellular organisms. It plays critical roles in development and immunity, as well as cancer and neurodegenerative disease. Apoptosis is accompanied by complex cascades of intracellular events that may include the activation of pro-apoptotic Bcl-2 family members, members of the Caspase family, and several nucleases.

## Angiogenesis

Angiogenesis is the process of new blood vessel formation, which is a natural event that occurs under both normal and pathological conditions. Angiogenesis is regulated by a very sensitive interplay of growth factors and inhibitors. Chemical stimulation of angiogenesis is performed by several growth factors, including FGFs, VEGFs, PDGFs, eprins, angiopoietins, TGF-beta and other.

## Tumor biomarker

Tumor markers are endogenous proteins or metabolites whose amounts or modifications are indicative of tumor state, progression characteristics, and response to therapies. They are present in tumor tissues or body fluids and encompass a wide variety of molecules, including transcription factors, cell surface receptors, and secreted proteins.

## Notch Signaling

The Notch pathway is highly conserved and has a wide range of physiological roles including regulating cell fate, proliferation, angiogenesis, cell survival, and the immune response. Aberrant Notch activity may also have complex and context-dependent effects on tumorigenesis. In mammals, canonical Notch ligands include members of the Delta-like (DLL) and Jagged families.

## WntSignaling

Wnt signaling pathway involves a large number of proteins that are required for basic developmental processes, such as cell-fate specification, progenitor-cell proliferation and the control of asymmetric cell division, in many different species and organs. The Wnt signaling pathway, as well as the Notch pathways, are thought to be involved in the occurrence of cancer stem cell.
